1 Control

Control structures direct the flow of logic in a program. For example, conditionals (ifelif-else) allow a program to skip sections of code, while iteration (while), allows a program to repeat a section.

1.1 If statements

Conditional statements let programs execute different lines of code depending on certain conditions. Let's review the if-eliese syntax:

Recall the following points:

- The else and elif clauses are optional, and you can have any number of elif clause.
- A conditional expression is a expression that evaluates to either a true value (True, a non-zero integer, etc.) or a false value (False, 0, None, etc.).
- Only the **suite** that is indented under the first if/elif that has a **conditional expression** that evaluates to True will be executed.
- If none of the **conditional expressions** are True, then the else suite is executed. There can only be one else clause in a conditional statement!

1.2 Boolean Operators

Python also includes the **boolean operators** and, or, and not. These operators are used to combine and manipulate boolean values.

- not returns the opposite truth value of the following expression.
- and short-circuits at the first False value and returns it. If all values evaluate to True, the last value is returned.
- or short-circuits at the first True value and returns it. If all values evaluate to False, the last value is returned.

```
>>> not None
True
>>> not True
False
>>> -1 and 0 and 1
0
>>> False or 9999 or 1/0
9999
```

1.3 Questions

1. Determine what the Python interpreter will output given the following lines of code.

```
>>> from operator import add, mul
>>> mul(add(5, 6), 8)
```

```
Solution: 88
```

```
>>> print('x')
```

```
Solution: x
```

```
>>> y = print('x')
```

```
Solution: x
```

>>> **print**(y)

```
Solution: None
```

```
>>> print (add(4, 2), print('a'))
```

```
Solution:
 а
 6 None
def foo(x):
     print(x)
     return x + 1
def bar(y, x):
     print(x - y)
>>> foo(3)
 Solution:
 4
>>> bar(3)
 Solution: Error
>>> bar(6, 1)
 Solution: -5
>>> bar(foo(10), 11)
 Solution:
 10
 0
```

2. Tommy will only wear a jacket outside if it is below 60 degrees or it is raining.

Write a function that takes in the current temperature and a boolean value telling if it is raining and returns True if Tommy will wear a jacket and False otherwise.

First, try solving this problem using an if statement.

```
def wears_jacket_with_if(temp, raining):
    """
    >>> wears_jacket_with_if(90, False)
    False
    >>> wears_jacket_with_if(40, False)
    True
    >>> wears_jacket_with_if(100, True)
    True
    """
```

```
Solution:
   if temp < 60 or raining:
       return True
   else:
      return False</pre>
```

Note that we'll either return True or False based on a single condition, whose truthiness value will also be either True or False. Knowing this, try to write this function using a single line.

```
def wears_jacket(temp, raining):
```

```
Solution:
return temp < 60 or raining
```

3. To handle discussion section overflow, Matt and other TAs may direct students to a more empty section that is happening at the same time.

Write a function that takes in the number of students in two sections and prints out what to do if either section exceeds 30 students.

Hint: You can do str (<number>) + <string> to concatenate a number and a string
def handle_overflow(s1, s2):

```
"""
>>> handle_overflow(27, 15)
No overflow
>>> handle_overflow(35, 29)
Move to Section 2: 1
>>> handle_overflow(20, 32)
Move to Section 1: 10
>>> handle_overflow(35, 30)
No space left in either section
"""
```

```
Solution:
    if s1 <= 30 and s2 <= 30:
        print("No overflow")
    elif s2 > 30 and s1 < 30:
        print("Move to Section 1:" + str(30 - s1))
    elif s1 > 30 and s2 < 30:
        print("Move to Section 2:" + str(30 - s2))
    else:
        print("No space left in either section")</pre>
```

4. Write a function that returns True if a positive integer n is a prime number and False otherwise.

A prime number n is a number that is not divisible by any numbers other than 1 and n itself. For example, 13 is prime, since it is only divisible by 1 and 13, but 14 is not, since it is divisible by 1, 2, 7, and 14.

Hint: use the % operator: x % y returns the remainder of x when divided by y.

```
def is_prime(n):
    """
    >>> is_prime(10)
    False
    >>> is_prime(7)
    True
    """
```

```
Solution:
```

```
if n == 1:
    return False
k = 2
while k < n:
    if n % k == 0:
        return False
    k += 1
return True</pre>
```

Alternatively, the while loop's conditional expression could ensure that k is less than or equal to the square root of n.
