1 Higher Order Functions

A **higher order function** (HOF) is a function that manipulates other functions by taking in functions as arguments, returning a function, or both.

1.1 Functions as Arguments

One way a higher order function can exploit other functions is by taking functions as input. Consider this higher order function called negate.

```
def negate(f, x):
    return -f(x)
```

negate takes in a function f and a number x. It doesn't care what exactly f does, as long as f takes in a number and returns a number. Its job is simple: call f on x and return the negation of that value.

1.2 Questions

1. Here are some possible functions that can be passed through as f.

```
def square(n):
    return n * n

def double(n):
    return 2 * n

What will the following Python statements output?
>>> negate(square, 5)
```

```
Solution:
-25
```

>>> negate(double, -19)

```
Solution:
38
```

>>> negate(double, negate(square, -4))

```
Solution:
32
```

2. Implement a function keep_ints, which takes in a function cond and a number n, and only prints a number from 1 to n if calling cond on that number returns True:

```
def keep_ints(cond, n):
    """Print out all integers 1..i..n where cond(i) is true

>>> def is_even(x):
    ...  # Even numbers have remainder 0 when divided by 2.
    ...  return x % 2 == 0
>>> keep_ints(is_even, 5)
2
4
"""
```

```
Solution:
    i = 1
    while i <= n:
        if cond(i):
            print(i)
        i += 1</pre>
```

1.3 Functions as Return Values

Often, we will need to write a function that returns another function. One way to do this is to define a function inside of a function:

```
def outer(x):
    def inner(y):
        ...
    return inner
```

The return value of outer is the function inner. This is a case of a function returning a function. In this example, inner is defined inside of outer. Although this is a common pattern, we can also define inner outside of outer and still use the same return statement.

```
def inner(y):
    ...
def outer(x):
    return inner
```

1.4 Questions

1. Use this definition of outer to fill in what Python would print when the following lines are evaluated.

```
def outer(n):
    def inner(m):
        return n - m
    return inner
>>> outer(61)
```

```
Solution:
<function outer.inner ...>
```

```
>>> f = outer(10)
>>> f(4)
```

```
Solution: 6
```

```
>>> outer(5)(4)
```

```
Solution:
```

2. Implement a function keep_ints like before, but now it takes in a number n and returns a function that has one parameter cond. The returned function prints out all numbers from 1..i..n where calling cond(i) returns True.

```
def keep_ints(n):
    """Returns a function which takes one parameter cond and
    prints out all integers 1..i..n where calling cond(i)
    returns True.

>>> def is_even(x):
    ... # Even numbers have remainder 0 when divided by 2.
    ... return x % 2 == 0
    >>> keep_ints(5)(is_even)
    2
    4
    """
```

2 Environment Diagrams

1. Draw the environment diagram for evaluating the following code.

```
def f(x):
    return y + x
y = 10
f(8)
```

```
Solution: https://goo.gl/rZnzaM
```

2. Draw the environment diagram for evaluating the following code.

```
